In particular, we show that a weak estimate on the probability of an annulus crossing implies that a random curve arising from a statistical mechanics model will.

One approach is to let the midpoint of the curve be a random point within  $(\text{curve length})/2$  of both of the starting point and the end point, and.

I have used the formulation "are algorithms already known ", because I have found one, Random Curves seems to be Random Curves to produce all those curves. It is sort of BM conditioned to end at a given point at a given time. Following the same idea as before, the uniform distribution over such paths converge under appropriate scaling to what is called Brownian bridge.
